## Sitting

### ■ Serratus Anterior Strength

Figure A: When the arm is raised in flexion, to position the scapula for the serratus test, the scapula does not move to the normal position of abduction. (see p. 333.) However, the Serratus appears to test strong in that position (probably because of over development of shoulder flexors). Figure B below shows the same subject. The winging of the scapula clearly indicates weakness of the serratus anterior.

Figure B: The scapula can be brought forward to almost normal abduction if the subject relaxes the weight of the arm and allows the examiner to draw the arm diagonally forward into the test position.

Figure C: The scapula cannot hold the abducted and upwardly rotated position when the examiner releases the arm, and the subject attempts to hold it in position.

---

---

## Supine

### ■ Shoulder Flexion – Latissimus Dorsi

- Full flexion (180°) with lumbar spine flat
- Scapula does not protrude more than 1/2 beyond posterolateral aspect of the thorax

### ■ Pectoralis Major Length – Sternal head

- Abduction (135°) – arm rest on the table
- Watch out for anterior/superior glide of the humeral head

### ■ Pectoralis Major Length – Clavicular head

- Abduction (90°) – arm rest on the table
- Watch out for anterior glide of the humeral head

---

---

## Limited Shoulder Internal Rotation

---

---

---

---

---

---

---

---

## Supine

### ■ Shoulder External Rotation

– 90° with arm abducted (90°) with minimum movement of the scapula

- Anterior/superior glide of humeral head – stiff of the lateral rotators, laxity of anterior joint capsule
- Less than 90° - shortness of Teres major, subscapularis, pectoralis major (Clavicular)

### ■ Biceps Length Test

■ Horizontal Adduction – posterior capsule

■ Upper Cervical Flexors Strength

## External Rotator - Performance

Starting Position

End Position

---

---

---

---

---

---

---

---

## Prone

### ■ Lower Trapezius Performance

- Able to maintain scapular upward and adducted position and lateral rotation of humerus with shoulder 135° abduction against maximum resistance
- Difficulty passively move arm into the test position – stiff/tight of pectoralis minor

---

---

---

---

---

---

---

---

## Prone

### ■ Lower Trapezius Performance

- Unable to maintain the test position, give ~ 10-15° - long lower trapezius
- Unable to tolerate maximum resistance at any position – weak
- Shoulder elevated – dominant Upper trapezius
- Scapular downward rotation or humerus medial rotation – rhomboids dominant

---

---

---

---

---

---

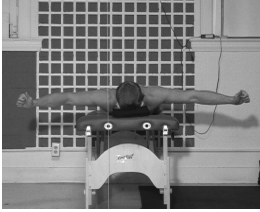

---

---

**Prone**

■ **Middle Trapezius Performance**

- Able to maintain scapular upward and adducted position and lateral rotation of humerus with shoulder 90° abduction against maximum resistance
- Unable to maintain the test position, give ~ 10-15° - long middle trapezius

---

---

---

---

---

---

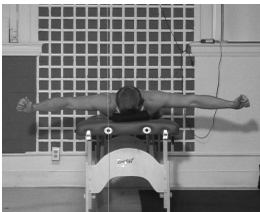

---

---

**Prone**

■ **Middle Trapezius Performance**

- Unable to tolerate maximum resistance at any position – weak middle trapezius
- Shoulder elevated – dominant Upper trapezius
- Scapular downward rotation or humerus medial rotation – rhomboids dominant
